ABSTRACT

ROAD ACCIDENTS AND DATA ANALYSIS (INDIA)

Road accidents are one of the major causes of injuries and loss of life in India. Many accidents happen because of factors such as poor road conditions, bad weather, speeding, traffic rule violations, and careless driving. The main purpose of this project is to study road accident data and identify the important factors that contribute to accidents. The dataset used in this project is the India Road Accidents Dataset collected from the Ministry of Road Transport and Highways (MoRTH). It contains 240 records with 25 attributes, including date and time, state, district, road type, weather, vehicle type, driver details, speed, accident severity, injuries, fatalities, and accident causes.

This project is developed using Python in Google Colab with the help of libraries such as Pandas, NumPy, Matplotlib, and Seaborn. The data is cleaned, processed, and analyzed using Exploratory Data Analysis (EDA), and the results are presented through easy-to-understand graphs and visualizations. The project helps identify accident patterns, high-risk conditions, and common causes of road accidents. The insights obtained from this analysis can support road safety awareness, improve decision-making, and help authorities plan effective measures to reduce accidents and make roads safer for everyone.
